<sup>6</sup> Thermal efficiencies are highly dependent on product mix.

7 The indirect liquefaction processes shown here may be Considered as gasification processes for SNG, with the major coproduct being galosine, e.g., for the "Fischer-Tropsch process" shown, the yield of SNG is 1.45 BOE/ton of coal, with a gasoline yield of 0.58 BOE/ton of coal. It is thus not representative of the SASOL-II process which emphasizes the production of liquid fuels.

<sup>8</sup> Direct thermal equivalent value (thermal efficiencies are highly dependent on product mix (see Section 7. 5).

### 3.4.1. General

**Oil** shale resources **vary** widely in their oil yields. High grade shale is normally defined as a deposit that averages 30 or more gallons of oil per ton of shale. Low grade shale averages 10 to 30 gallons per ton<sup>0</sup> (Reference No. 7). Several factors determine whether or not an oil shale deposit *is recoverable*. These include oil yield (usually equal or above 20 gallons per ton), zone thickness, overburden thickness, the presence of other materials *in the shale*, availability of needed resources such as water and services, and location relative to markets.

There are two major routes for converting oil shale to liquid or gaseous fuels. They are:

- Conventional mining followed by surface retorting (heating) , and
- 2. In situ (in place) retorting

In addition, there is modified in situ. In this process, the perme ability (i.e., void volume) of oil shale deposits is increased in order to enhance the in situ retorting by removing some of the shale. The methods of rein@ or increasing the permeability of the oil shale deposits are explained in reference &.

### 3.4.2. Surface Retorting

9

In surface retorting of oil shale, the heating takes place above ground. The shale is crushed to the right size, and fed into a retorting vessel. Heating the shale to between 800°F and 1000°′F removes abut 75 percent of the kerogen from the shale (Reference No. 8). Different retorting precesses apply heat to the shale in different ways. Gas or non combustible solids such as sand or ceramic balls can be used as heat carriers. The vapor produced during the heat@ is condensed to form crude shale oil. It can be further upgraded and refined to produce more marketable products.

As a generic surface retorting process, TOSCO II is described. Its schematic diagram is given in Figure 3.10 (Reference No.\_8).

Ø

Shale deposits yielding less than 10 gallons of oil per ton are normally omitted from USGS resource estimates.

Raw oil shale is crushed to 1/2 inch and preheated to  $500^{\circ}$  F. It is mixed with hot ceramic balls 3/4 inch in diameter and at  $1200^{\circ}$ F in a retorting Pyrolysis drum (Reference No. 25). About two tons of balls mix with every ton of shale. The oil shale is heated to  $900^{\circ}$ F, releasing hydrocarbon vapors from the kerogen. The spent shale and the balls pass to the sealed accumulator vessel, in which the balls are separated from the shale by a heavy duty rotating cylinder with numerous holes. The balls are lifted by a bucket elevator to the gas fired ball heater, which heats the balls to  $1270^{\circ}$ F by direct contact heat exchanger. The spent shale goes through

### FIGURE 3.10

#### The TOSCO II Oil Shale Retorting System

SOURCE Oil Shale Retorting Technology prepared for OTA by Cameron Engineers. Inc. .1978

a special heat exchanger which cools the shale for disposal and produces steam for plant use. Then the spent shale is quenched with water and moisturized to 14 percent, a level proper for disposal.

Hot flue gas from the ball heater is used to lift raw shale to a point at which it can subsequently flow by gravity into the pyrolysis drum. The flue gas also heats the raw shale to approximately 500°F.

Table 3.10 (Reference No. 25 ) summarizes the basic material balance for a TOSCO II retort module.

### 3.4.3 Modified In Situ Retorting

Occidental modified in situ oil shale retorting process is selected as representative. It involves the mining out of about 10 to 25 percent of the shale deposit. This mined portion would presumably be retorted by one of the surface retorting processes, or if its oil content is too low, will be treated as waste (Reference No. 37).

Figure 3.11 (Reference No. 8 ) represents in schematic form a generic modified in situ oil shale retorting process. 'Figure 3.12 (Reference No. 37 ) is a more detailed description of the Occidental modified in situ retorting process. As observed in Figure 3.12 , in steps A or the pre-detonation phase, drifts (chambers) are excavated at the top and bottom of the shale deposit, which is about 300 feet-thick. An interconnecting shaft is dug to connect the drifts. Rooms with a volume of about 15 to 20 percent of the eventual volume of the planned chamber are then mined. Shot holes are drilled to allow blasting of the shale oil to produce the desired fragmentation.

In the burn phase, the explosives in the shot holes are detonated. A rubble-filled chamber is created which can function as a batch retort. The percentage of void space and the particle size distribution of the rubble are a function of the explosive loading. Connections are made to air/gas recycle and air supply compressors. An outside heat source (e.g., off gas or oil from other retorts) is used for heating the rubble at the top of the retort. Oil shale and hydrocarbon gases are produced which move downward. Residual carbon is left on the spent shale.

The retorting reaction is terminated after a predetermined amount of the rubble has been retorted by halting the external heating supply. The residual carbon is utilized to continue the combusion process, which now does not need external heating. The flame front moves downwards, preceded by the liquid and gaseous products retorted from the shale by the hot, oxygen-deficient combusion gases. The liquid hydrocarbons collect in a sump, from which they are pumped to the surface. The gaseous by-products are used partially, with steam, as a recycle stream to control the oxygen content of the inlet gas. The four distinct zones that develop during the retorting are shown in Figure 3.11.

Table\_ 3.13 \_(Reference No. 17 ) summarizes the components, resource requirements, and potential impacts of modified in situ retorting.

# 3.5 comparison of the Various Synfuel Systems With Respect to Resource Requirements $\frac{10}{10}$

In order to estimate the resource requirements of the coal and oil shale fuel cycles we need first to assess their energy utilization efficiencies. These are summarized in Table 3.14.

The *resource* requirements of coal and oil shale energy systems per 10<sup>6</sup> Btu of product delivered to end user are given in Tables 3.15 and 3.16. Tables 3.17 and 3.18 convert these requirements to energy systems producing 50,000 barrels of oil equivalent per day.

Manpower requirements for operating and maintenance labor of coal conversion plants are given in Reference 29.

They are:

Plant operatorsOperating supervisorsMaintenance laborMaintenance labor supervisors30Administration30Total355

These manpower requirements are for a basic (ESCOE) coal conversion plant that consumes 25,000 tons of coal per day with 22.4 million Btu/ton and produces 50,000 bbl/day liquids output.

Very considerable variations exist in the literature in respect to manpower requirements for the other phases of the fuel cycle. They depend on such variables as methods of mining, location of mine, kind of transportation system and extent of beneficiation. A table indicating the ranges of variables is given in the footnote in respect to the conversion plants.

10 Limitations of Data Sources: Evaluations carried out in this report are often sub ject to great uncertai nties because:

(1) The information available is only of preliminary nature. There are no full scale operating synfuel plants in the U.S. (subject to U.S. siting considerations), so that data needs to be extrapolated from pilot plants with many uncertainties of scale and dissimilarities associated with the extrapolation, as well as specific siting and f eedstock characteristics discussed below.

10 (cent'd)

(2) There are variations among sources which are often due to different assumptions or local influences. Changes in design account for some differences as the technology changes and the environmental regulations change. Many of the assumptions are not stated - or even referenced. Budget and time limitations, however, nessitate the need to use exist& data bases, rather than the development of new data.

Even estimating the range of uncertainties is often a value judgement **process**, **unless more**extensive on-site interviewing with site and process specific sources of information are developed.

Resource Utilization Efficiencies of Generic Synthetic Fuel Energy Systems

Table 3.4

E. J. Bentz & Associates SOURCE:

### Notes for Table 3.14

- a. Estimates of losses of coal and oil shale from beneficiation (in terms of Btu's) vary broadly among authors, depending on the assumed degree of upgrading and the kind of coal or oil shale used. Estimates vary from 0% (Reference 37a) ; 2.7-3.6% (Reference 7) ; and 12.5% for intensive beneficiation (Reference No. 17) .
- b. Average value of losses are 1.5% (time from Reference No. 7) . In the case of oil shale, where distances are shorter, 0 .5% is assumed.
- c. The @et efficiencies (rather than the process efficiencies) were used. The efficiencies for coal conversion processes are derived from Roger and Hill. (Reference 29) . In the case of H-Coal, the syncrude efficiency was used. In the case of oil shale retorting processes, the efficiencyes are derived from DOE (Reference No. 17) .
- d. Data on efficiencies of upgrading and refining syncrudes is very limited and unreliable (see Section 1.7) .
- e. N.A. means not applicable.
- Overall yields for SRC II of finished fuels range between 83 and 98 f. liquid volume percent of SRC II syncrude, depending on the product slate and how refinery fuel and hydrogen plant feed are supplied. An average of the net product yields ranging between 88 and 91 was assumed (Reference No. 22) . However, these values apparently do not include coal use for the\_production of hydrogen needs for the upgrading process. If coal-derived hydrogen is to be used (as against hydrogen from nuclear fission or from biosynthesis), then the upgrading and refining efficiencies for coal conversion products become 75 percent. However, in some cases it may be expected that all of the hydrogen and energy required for the Upgrading/refining process would be obtained from residuals, higher boiler fractions, and methane produced in the process or plant refinery(which may include the use of Petroleum • In the case of indirect liquefaction derived vacuum Processes, all the needed hydrogen is accounted for in the gasifier, and higher upgrading efficiencies can be achieved, depending on product slate .
- 9" Derived from Reference 26a. However, MIS oil is easier to upgrade, so that higher efficiency may be in order.
- h. Derived from Reference <u>17</u>.
- i. Derived from Reference 7.
- j\_ Derived from Reference 7 and 10.

Table 3.15 Fossil Carbon Consumption of Generic Synthetic Fuel Energy Systems (J

SOURCE: E. J. Bentz & Associates

### Notes to Table 3.15

- a This table summarizes the consumption of fossil carbon contained in the feedstocks or products during the various phases of the various synfuel cycles.
- b The numbers in the table are based on the following assumptions:
  - (i) The resource utilization efficiencies are those developed in Table 3.14.
  - (ii) The carbon content of bitumimous coal averages 87.8%, lignites -72. 5% and sub-bituminous~ reals - 73. 5%. The carbon content of the kerogen (i. e., crude shale oil) averages 80. 5%. (Ref. 26b) . For convenience, an average figure of 80% for the carbon content of coals and kerogen is used.
  - (iii)The loss in fossil carbon is directly proportional to the loss in coal or kerogen.
  - (iv) The Btu content of a ton of coal is  $24 \times 10^6\,{\rm Btu}$  and of ton crude shale oil is  $36 \times 10^6\,{\rm Btu}.$
- c A sample calculation for medium Btu coal gasification is as follows:

A ton of feedstock bituminous coal has 24x.10° Btu, of which 18. 34x10° to 19. Olx10° Btu is delivered to the end users (74.4 to 79. 2% overall energy efficiency - see Table 3.14). Since a ton of feedstock coal. has 80% fossil carbon content, and 20.8% to 23.6% of it is consumed during the medium Btu coal gasification fuel cycle, (see Table 3.14), the total fossil carbon consumption of the cycle is between 0.1664-0.1888 tons per 18.34x10 to 19. Olx10 Btu delivered to end users.This translated to 0.009 to 0.010 tons of fossil carbon per 10° Btu.

### Notes to Table 3.16

- a The water required for mining and preparation of the coal or shale and for the disposal of ash or spent shale is a function of location, mainly through the amount of material that must be mined or disposed; and the degree of attested surface reclamation. Assuming 2/3 of coal is surface-mined and 1/3 is undergroundd mined, water consumption for surface mining ranges between 0.55 and 0.98 gallons per 10<sup>b</sup> Btu of product, and for underground mining - 0.75 gallons per 10<sup>b</sup> Btu of Product (Reference No. 17).
- b Assume 2/3 of oil shale is surface mined and 1/3 is underground mined. Water consumption or both kinds of operations range between 0.7 and 1.1 gallons per 10<sup>6</sup> Btu of **product (Reference No. 17)**.
- c Consumption of 1.2 gallons of water 10<sup>6</sup> Btu Of product is assuned for beneficiation of coal (Reference No. 17) and none for shale oil.
- d Consumption of water for the conversion of feedstock to fuels depends principally on the overall plant conversion efficiency, degree of water recycling, and the water content of the coal or shale. Consumption figures range from 13-24 gallons per 106 Btu of product for coal gasification; 7-26 for direct coal liquefaction; 13-26 for indirect coal liquefaction; 9-32 for surface shale retorting; and 9-13 for modified in situ shale retorting (Derived from References 17, 37b,c).
- e Water consumption for upgrading and refining is not available in the literature. The estimates presented for shale oil upgrading are based on private conversation with Mr. Bobby Hall and Ray Young of the American Petroleum Institute 3/81. For shale oil 100 gallons per barrel are needed to make the raw shale oil suitable for pumping, and 40 more gallons per barrel to convert it to transportation fuels. Polling of a large number of oil companies and API experts did not result in water consumption estimates for upgrading of coal liquids (namely: Robert Howell, Bonner and Moore, Fred Wilson Texaco, Patton, Nanny, Hall and Young of API 3/81).
