### [57] ABSTRACT

Substantially C<sub>2</sub>+ alkane hydrocarbons are produced from mixtures of CO and H<sub>2</sub> by contacting same, at elevated temperature, with a catalyst comprising a mixture of iron carbide and ilmenite supported on titania wherein the ratio of the iron present in said supported iron carbide and ilmenite, calculated as Fe<sub>2</sub>O<sub>3</sub>, to the surface area of the titania support ranges from about 2×10<sup>-3</sup> to 25×10<sup>-3</sup> grams per square meter.

EFFECT OF IRON ON TITANIA CONCENTRATION  
ON CO HYDROGENATION ACTIVITY

## PRODUCTION OF ALKANES FROM MIXTURES OF CO AND H<sub>2</sub>

### CROSS REFERENCE TO RELATED APPLICATIONS

This application is a continuation-in-part of U.S. Ser. No. 511,651 filed on July 7, 1983, now abandoned.

### BACKGROUND OF THE INVENTION

#### 1. Field of the Invention

This invention relates to a Fischer-Tropsch process using a catalyst comprising a mixture of iron carbide and ilmenite supported on titania. More particularly, this invention relates to a process for producing substantially alkane hydrocarbons from mixtures of CO and H<sub>2</sub> using a catalyst comprising a mixture of iron carbide and ilmenite supported on titania wherein the ratio of the iron present in said supported iron carbide and ilmenite, calculated as Fe<sub>2</sub>O<sub>3</sub>, to the surface of the titania support ranges from about 2 to 25 milligrams per square meter of titania support surface area.

The use of iron-titania mixtures as Fischer-Tropsch catalysts for converting mixtures of CO and H<sub>2</sub> to hydrocarbons is well-known to those skilled in the art. For example, U.S. Pat. No. 2,543,327 discloses titania promoted iron oxide for Fischer-Tropsch synthesis wherein the iron oxide is in the form of naturally occurring magnetite and preferably as Alan Wood ore. In this disclosure a typical catalyst is shown as prepared by mixing about 13,600 grams of Alan Wood ore with 98 grams of titania and 216 grams of potassium carbonate used as a promoter. The ratio of hydrogen to carbon monoxide disclosed as being preferably at least 2/1 and the results show that the catalyst has relatively poor activity with a large selectivity towards the production of methane and very little selectivity towards the production of C<sub>2</sub>+ hydrocarbons. That is, the Fischer-Tropsch product was primarily methane. Similarly, British Pat. No. 1,512,743 also discloses a titania promoted, massive iron type of Fischer-Tropsch catalyst wherein iron oxide is mixed with titanium oxide, zinc oxide and potassium carbonate with the resulting mixture being sintered and then reduced for many hours at 500° C. Although this catalyst has relatively reasonable activity with regard to conversion of the CO and H<sub>2</sub> mixture, the product was primarily (i.e., about 73%) olefinic, unsaturated C<sub>2</sub>/C<sub>4</sub> hydrocarbons and with only 10% of C<sub>2</sub>/C<sub>4</sub> saturated hydrocarbons or alkanes being produced. U.S. Pat. Nos. 4,192,777 and 4,154,751 while directed towards the use of potassium promoted Group VIII metal cluster catalysts in Fischer-Tropsch synthesis reactions, suggest that iron supported on titania would be useful Fischer-Tropsch catalysts but do not disclose the preparation of same. In their examples, they disclose iron on various supports other than titania with the amount of iron on the support generally being less than about 5 percent. U.S. Pat. No. 4,261,865 discloses an iron titanate-alkali metal hydroxide catalyst for preparing alpha-olefins from mixtures of CO and H<sub>2</sub>. That is, the catalyst is not iron supported on titania along with an alkali metal hydroxide but rather an iron titanate compound.

Another example of a titania-promoted massive iron catalyst for Fischer-Tropsch synthesis may be found in the Volume 17, No. 3-4 React. Kinet. Catal. Lett., pages 373-378, (1981) titled "Hydrocondensation of CO<sub>2</sub> (CO) Over Supported Iron Catalysts". This article

discloses an iron oxide, titania, alumina, copper oxide catalyst promoted with potassium. Similarly, in European patent application EP 0 071770 A2 Fischer-Tropsch catalysts are disclosed which include iron titania catalysts wherein the iron to titania ratio can be greater than 1/10. The actual iron-titania catalyst is not an iron supported on titania catalyst but an iron/titania catalyst produced by a coprecipitation technique wherein the active iron catalytic component is distributed throughout a titanium oxide matrix. Thus, the resulting catalyst was not iron supported on titania but rather a bulk phase iron/titania mixture which, when used for Fischer-Tropsch synthesis, produced predominately olefins. The amount of olefins produced was generally greater than about 80% of the total hydrocarbon product.

With regard to iron/titania catalysts for Fischer-Tropsch wherein the iron is supported on titania, a 1982 article by Vannice, *Titania-Supported Metals as CO Hydrogenation Catalysts*, J. Catalysis, v.74 p.199-202 (1982) discloses the use of an iron/titania catalyst for Fischer-Tropsch synthesis wherein the amount of iron, calculated as metallic iron, is 5 percent of the iron/titania composite and the catalyst shows extremely little activity for Fischer-Tropsch synthesis.

An article by Reymond et al, *Influence of the Support or of an Additive on the Catalytic Activity in The Hydrocondensation of Carbon Monoxide by Iron Catalysts in "Metal-Support and Metal-Additive Effects in Catalysis*, B. Imelik et al. (Eds), Elsevier, Netherlands, p.337-348 (1982) also discloses the use iron/titania Fischer-Tropsch catalysts wherein the iron is supported on the titania. The iron/titania catalysts disclosed contain about 9.5 weight percent iron on titania and the activity of the resulting catalysts is presented as a function of the activation pretreatment of the iron/titania catalyst precursor. Thus, it was disclosed that if the precursor was pretreated in either helium or hydrogen at 250° C. there was relatively little activity for Fischer-Tropsch synthesis. Similarly, another composite treated in hydrogen for 15 hours at 500° C. showed no activity whatsoever. It is important to note that the catalytic activity was expressed only as a function of methane production using a 9/1 mole ratio of H<sub>2</sub>/CO at one atmosphere pressure and a reaction temperature of 250° C.

### SUMMARY OF THE INVENTION

It has now been discovered that substantially C<sub>2</sub>+ alkane hydrocarbons can be produced from mixtures of CO and H<sub>2</sub> using a catalyst comprising a mixture of iron carbide and ilmenite supported on titania. Those skilled in the art know that ilmenite is an iron titanate having the formula FeTiO<sub>3</sub>. The ratio of the iron present in said supported iron carbide and ilmenite, calculated as Fe<sub>2</sub>O<sub>3</sub>, to the surface of the titania support will generally range from about 2 to 25 milligrams per square meter. By substantially C<sub>2</sub>+ alkane hydrocarbons is meant that more than about 50 wt.% of the hydrocarbon products, including methane, are alkane C<sub>2</sub>+ hydrocarbons. In a preferred embodiment the catalyst will be treated with CO at elevated temperature prior to use.

### BRIEF DESCRIPTION OF THE DRAWING

The FIGURE is a plot of CO conversion rate as a function of the iron loading level of a catalyst of this invention.

## DETAILED DESCRIPTION

It is essential to this invention that the mixture of iron carbide and ilmenite is supported on and not merely mixed with the titania support. The iron loading on the titania support must be sufficient to form a mixture of both iron carbide and ilmenite. In general, it has been found that this will occur if the iron loading, calculated as  $\text{Fe}_2\text{O}_3$ , is at least about 2 milligrams per square meter of titania support surface. It has been found that if the titania doesn't support at least about 2 milligrams of iron, calculated as  $\text{Fe}_2\text{O}_3$ , per  $\text{m}^2$  of titania support surface, the catalyst will possess little or no activity for conversion of mixtures of  $\text{CO}$  and  $\text{H}_2$  to hydrocarbons. On the other hand, it has been found that selectivity of the catalyst to alkane formation rapidly decreases if more than about 25 milligrams of iron, calculated as  $\text{Fe}_2\text{O}_3$ , per  $\text{m}^2$  of  $\text{TiO}_2$  support surface is loaded onto the titania support. Preferably, the amount of iron present in the iron carbide and ilmenite mixture on the titania support will range from about 2.8 to 8.3 milligrams of iron calculated as  $\text{Fe}_2\text{O}_3$ , per  $\text{m}^2$  of titania support surface.

The catalyst will be prepared by depositing a suitable iron precursor component onto the titania support from a precursor solution using any of the well-known techniques such as incipient wetness, multiple impregnation, pore-filling etc., the choice being left to the convenience of the practitioner. As has heretofore been stated, it is important for the iron precursor to be deposited onto the titania support as opposed to other methods for catalyst preparation such as co-precipitation or physical mixtures. After impregnation, the impregnate is dried to remove excess solvent and/or water therefrom. The dry impregnate can then be converted to a catalyst of this invention employing a number of different methods. In one method, the impregnate will be converted directly to a catalyst of this invention by contacting same with a  $\text{CO}$  containing reducing gas, preferably a reducing gas containing a mixture of  $\text{CO}$  and  $\text{H}_2$ . Thus, it will be appreciated to those skilled in the art that the catalyst of this invention can be formed from the impregnate in-situ in a Fischer-Tropsch hydrocarbon synthesis reactor. However, it is preferred to employ a sequential treatment of first contacting the dry impregnate with an  $\text{H}_2$  containing reducing gas that does not contain  $\text{CO}$  to reduce the impregnate, followed by contacting the reduced impregnate with  $\text{CO}$  or a  $\text{CO}$  containing gas such as a mixture of  $\text{CO}$  and  $\text{H}_2$  to form the catalyst of this invention. As a practical matter, it may be commercially advantageously to form the catalyst of this invention by subjecting the impregnate to calcining to convert the supported iron precursor component to iron oxide, followed by subsequent reduction and formation of the catalyst of this invention.

Promoter metals such as potassium or other alkali metals may be added via impregnation, etc. before the composite is contacted with a reducing atmosphere and/or  $\text{CO}$  containing gas to form the catalyst of this invention. In general, the amount of promoter metal present will range from about 0.5 to 5 wt.% based on the amount of iron (calculated as  $\text{Fe}_2\text{O}_3$ ) supported on the titania.

If one desires to obtain a catalyst of this invention via a supported iron oxide route, then the dry impregnate will be calcined in air or other suitable oxidizing atmosphere at a temperature of from about  $120^\circ$  to  $300^\circ$  C.

for a time sufficient to convert the supported iron precursor component to iron oxide. After the iron/titania impregnate has been calcined to convert the supported iron precursor compound to iron oxide, the iron oxide/titania composite, with or without one or more promoter metals, is reduced in a hydrogen-containing, net-reducing atmosphere at a temperature broadly ranging from about  $300^\circ$ – $500^\circ$  C. for a time sufficient to convert the iron oxide to metallic iron. It has been found that if one tries to reduce the iron oxide/titania composite at a temperature below about  $300^\circ$  C., (i.e.,  $250^\circ$  C.), the catalyst of this invention will not subsequently be formed.

Irrespective of the route one employs to form a catalyst of this invention, whether by reduction followed by contacting with  $\text{CO}$ , direct formation of the catalyst or through the supported iron oxide route, it is important not to contact the composite with a reducing gas at temperatures above about  $500^\circ$  C.

Reduction temperatures exceeding about  $500^\circ$  C. will produce a catalyst which exhibits relatively low  $\text{CO}$  hydrogenation activity with less than 50% of the  $\text{C}_2+$  hydrocarbons being alkanes. Further, even at a  $500^\circ$  C. reduction temperature a less effective catalyst will be produced if the reduction occurs for too long a time, i.e., about ten hours or more. Thus it will be appreciated that the temperature range for reducing the composite to form a catalyst wherein at least a portion of the supported iron is in the reduced form cannot be critically quantified with any degree of precision inasmuch as there exists a time-temperature continuum for proper reduction.

In a preferred embodiment of this invention, the catalyst composite will first be reduced, followed by contacting with  $\text{CO}$  at temperatures ranging from about  $200^\circ$  to  $500^\circ$  C. and preferably  $200^\circ$  to  $400^\circ$  C. for a time sufficient to form a catalyst comprising a mixture of ilmenite and iron carbide supported on titania. It has been found that a  $\text{CO}$  treatment following hydrogen reduction dramatically improves the activity of the catalyst for  $\text{CO}$  conversion with only slight changes in product selectivity. A mixture of ilmenite and iron carbide on the titania support will also be achieved by treating the calcined iron/titania composite with a mixture of  $\text{CO}$  and  $\text{H}_2$ , but it is preferred to use the sequential treatment comprising hydrogen reduction followed by  $\text{CO}$  treatment. Further, when using this sequential treatment to produce a catalyst of this invention, it is preferred that the temperature used for the  $\text{CO}$  treatment be lower than that used for the hydrogen reduction. Thus, in general the  $\text{CO}$  treatment will occur at a temperature of about  $100^\circ$  to  $200^\circ$  C. lower than the temperature used for the hydrogen reduction.

It has also been discovered that, if a catalyst of this invention has been prepared by hydrogen reduction and then contacted in-situ, in a reactor, with a feedstream comprising a mixture of  $\text{CO}$  and  $\text{H}_2$  to form a catalyst of this invention, the activity of the so formed catalyst will be substantially increased by reducing or eliminating the hydrogen content of the feedstream, raising the temperature in the reactor an additional  $50^\circ$  to  $150^\circ$  C. for a short period of time (i.e., 3–5 hours), followed by reestablishing the original reaction conditions.

Predominantly  $\text{C}_2+$  alkane hydrocarbons are produced from mixtures of  $\text{CO}$  and  $\text{H}_2$  by contacting said mixtures with the catalyst of this invention at temperatures ranging from about  $200^\circ$  to  $350^\circ$  C. and preferably from about  $250^\circ$ – $320^\circ$  C. The reaction pressure will

generally range from about 100–500 psig and more preferably from about 150–300 psig, although pressures outside this range may be used if desired. However, if one goes too low in pressure (i.e., <50 psig), catalyst activity will be greatly reduced and methane production will predominate. Upper pressure limits will generally be dictated by economic considerations. The H<sub>2</sub>/CO mole ratio in the reaction zone will generally range from about 1/2 to 3/1, preferably from about 1/2 to 2/1 and still more preferably from about 1/2 to 1/1.

The invention will be more readily understood by reference to the following examples of which Examples 3 and 5 are directed to the claimed invention.

## EXAMPLES

### EXAMPLE 1

In this experiment a number of iron supported on titania catalysts were prepared by impregnating, at room temperature, a titania powder (Degussa P-25) with aqueous solutions of ammonium trisoxalato ferrate containing different amounts of the iron salt. The resulting impregnates were dried in air. After drying, each impregnate was ground to a powder and calcined in air for at least one hour at 200° C. to form an iron oxide/titania composite. A 1–2 cc. sample of each composite was loaded into a  $\frac{3}{8}$  inch O.D. stainless steel tube reactor. The reactor was flushed with hydrogen at room temperature and atmospheric pressure. The reactor temperature was then brought up to 450° C. in flowing hydrogen (90 cm<sup>3</sup>/min) and maintained at these conditions for 1–2 hours. After this, the reactor was cooled to a temperature of 300° C. and the pressure increased to 150 psig. The hydrogen was then replaced with a 3/1 mole mixture of H<sub>2</sub>/CO at a flow rate (standard hourly velocity) of 3600 v/v/hr. The exit gas from the reactor was fed into a gas chromatograph for on-line analysis of C<sub>1</sub>–C<sub>15</sub> hydrocarbons, CO, CO<sub>2</sub>, and N<sub>2</sub>.

The results of this experiment are plotted in the FIGURE in terms of CO conversion rate as a function as the iron loading level on the catalyst calculated as grams of Fe<sub>2</sub>O<sub>3</sub> per m<sup>2</sup> of TiO<sub>2</sub> surface area. These results dramatically illustrate an unexpected, minimum critical iron loading level for Fischer-Tropsch activity of about  $2 \times 10^{-3}$  grams of Fe<sub>2</sub>O<sub>3</sub> per m<sup>2</sup> of titania.

### EXAMPLE 2

Another catalyst of this invention was prepared, consisting of  $2 \times 10^{-3}$  grams of iron, calculated as Fe<sub>2</sub>O<sub>3</sub>, per square meter of titania support. This was prepared by mixing an aqueous solution of ferric nitrate with a titania slurry (Degussa P-25), with stirring, for an hour at 25° C. The mixture was then heated to 120° C. for a three hour period at a pressure of 45 mm Hg pressure to remove the solvent and form a solid impregnate. The impregnate was then ground to a powder and dried overnight at 120° C. under vacuum, followed by drying in air overnight at 130°–150° C. The dried, calcined, powdered composite was then pelletized at 5000–15000 psi, crushed and sieved to 20–80 mesh particles.

8.8 cm<sup>3</sup> of the calcined catalyst composite was loaded into a  $\frac{1}{2}$  inch O.D. stainless steel tubular reactor which was then purged with hydrogen at 50° C. and atmospheric pressure. The pressure was then raised to 100 psig and a 9/1 mole mixture of H<sub>2</sub>/N<sub>2</sub> introduced into the reactor at a rate of 100 cc/min. The temperature in the reactor was then increased to 500° C. at a rate of 6° C./min. and was maintained at these conditions for five hours to form the catalysts. The H<sub>2</sub>/N<sub>2</sub> stream was then

replaced with a Fischer-Tropsch feedstream consisting of a 1/1 mole ratio of CO/H<sub>2</sub> diluted with 10 volume percent nitrogen. The reactor pressure had been raised to 300 psig and the temperature reduced to 270° C. before the gas feed was introduced at a rate (standard hourly space velocity) of 500 v/v/hr. As in Example 1, the reactor effluent was fed into a gas chromatograph.

The results of this experiment are set forth in Table 1 and show that 57.2 percent of the hydrocarbon products were alkanes with less than 25 percent methane production.

### EXAMPLE 3

The experiment of Example 2 was repeated with the exception that the calcined catalyst composite was sequentially treated first with the 9/1 mole mixture of H<sub>2</sub>/N<sub>2</sub> for five hours at 500° C. and then with a 9/1 mole ratio mixture of CO/N<sub>2</sub> for five hours at 350° C. The results of this experiment, also shown in Table 1, demonstrate the beneficial affects of the sequential hydrogen CO treatment in terms of increased CO conversion, higher alkane yield, and greater C<sub>5</sub>+ alkane yield.

### EXAMPLE 4

Another catalyst of this invention was prepared containing  $4.2 \times 10^{-3}$  grams of iron, calculated as Fe<sub>2</sub>O<sub>3</sub>, per m<sup>2</sup> of titania support by adding a solution of 38.16 grams of ammonium trisoxalato ferrate in 60 milliliters of distilled water to 44.8 grams of titania (Degussa P-25). The resulting mixture was dried at 65° C. in air for three days. The resulting impregnated solid was ground to powder and heated at 200° C. for six hours to decompose the iron complex and calcine the impregnate. The resulting powder was subsequently cooled to room temperature and impregnated with 0.157 grams of potassium carbonate dissolved in 10 ml water. The mixture was dried in air at 120° C. for one hour to produce a potassium promoted composite wherein the amount of potassium was 4.28 percent based on the iron content, calculated as Fe<sub>2</sub>O<sub>3</sub>, of the calcined composite.

The potassium containing composite was then pelletized, crushed and sieved to 20–80 mesh particles, 8.8 cc of which were loading into a  $\frac{1}{2}$  inch stainless steel reactor and treated using the procedure given in Example 2. The results, shown in Table 2, illustrate less than about 5 percent olefin production.

### EXAMPLE 5

Another catalyst of this invention was prepared following the procedure of Example 2 to form a calcined composite which was pelletized, crushed and sieved wherein the catalyst contained  $8.3 \times 10^{-3}$  grams of iron, calculated as Fe<sub>2</sub>O<sub>3</sub>, per square meter of titania support. This composite was reduced with a mixture of 20 percent hydrogen in helium for two hours at 450° C. and then cooled to 25° C. in the flowing gas. When room temperature was achieved, the hydrogen flow was stopped and oxygen was introduced into the flowing helium at a 2 percent level in order to passivate the reduced composite. X-ray diffraction patterns of this hydrogen reduced material showed TiO<sub>2</sub> (both anatase and rutile), FeTiO<sub>3</sub> (ilmenite) and Fe<sup>0</sup> (metallic iron). This same reduced sample was then treated with CO for one hour at 350° C. and cooled to room temperature in the same gas. After this, the sample was flushed with helium and then passivated with 3 percent oxygen in helium and the X-ray diffraction pattern measured

again. It was found that the CO treatment as used in Example 3, had no effect on the X-ray powder diffraction pattern of the titania and ilmenite, but caused the X-ray diffraction pattern of metallic iron to disappear. Also, a broadened pattern of iron carbide  $Fe_3C_2$  patterned after the CO treatment, indicating that CO converted the metallic iron to small particles of iron carbide.

TABLE 1

Composite C<sub>5</sub><sup>+</sup> determined by N<sub>2</sub> internal standard method.

What is claimed is:

1. A process for producing hydrocarbons, including alkane hydrocarbons, from gaseous mixtures of CO and H<sub>2</sub> comprising contacting said mixture, at a temperature ranging from about 200° to 350° C. and for a time sufficient to convert at least a portion of said feed to alkane hydrocarbons, with a catalyst comprising a mixture of iron carbide and ilmenite supported on titania wherein the amount of said supported iron present in said supported iron carbide and ilmenite, calculated as Fe<sub>2</sub>O<sub>3</sub>, is at least about  $2 \times 10^{-3}$  grams per square meter of titania support surface.

2. The process of claim 1 wherein said alkane hydrocarbons comprise greater than 50% of the hydrocarbons, including methane, produced by said process.

3. The process of claim 2 wherein said process occurs at a pressure of at least about 100 psig.

4. The process of claim 3 wherein the amount of supported iron present in said supported iron carbide and ilmenite, calculated as Fe<sub>2</sub>O<sub>3</sub>, ranges between about 2 to 25 milligrams of iron per square meter of titania support surface.

5. The process of claim 4 wherein said catalyst contains one or more alkali metal promoters present in said catalyst in an amount of from about 0.5 to 5 wt.% based on the amount of iron, calculated as Fe<sub>2</sub>O<sub>3</sub>, present on said catalyst.

6. The process of either of claims 3, 4 or 1 wherein the mole ratio of H<sub>2</sub> to CO in said gaseous mixture is between about 1/2 to 3/1.

7. A process for producing predominantly alkane hydrocarbons from gaseous feed mixtures of H<sub>2</sub> and CO comprising contacting said feed, at a temperature of from about 200° to 350° C. and for a time sufficient to convert with at least a portion of said feed to alkane hydrocarbons, with a catalyst comprising a mixture of iron carbide and ilmenite supported on titania, wherein the amount of iron present in said supported iron carbide and ilmenite, calculated as Fe<sub>2</sub>O<sub>3</sub>, is at least about  $2 \times 10^{-3}$  grams of iron per square meter of titania support surface, said catalyst having been formed by depositing an iron precursor compound on said titania support to form an iron/titania composite, calcining said composite to decompose said precursor compound and convert at least a portion thereof to iron oxide, followed by reducing said iron oxide/titania composite by first contacting same with hydrogen at a temperature of at least about 300° C. for a time sufficient to form a reduced composite and then contacting said reduced composite with CO at a temperature of at least about 200° C. for a time sufficient to form said catalyst.

8. The process of claim 7 wherein the amount of iron supported on said catalyst ranges between about 2 to 25 milligrams of iron per square meter of titania support surface.

9. The process of claim 8 wherein said catalyst has been contacted with CO at elevated temperature prior to use and after the composite has been reduced with hydrogen.

10. The process of claim 9 wherein said catalyst contains one or more alkali promoter metals wherein the amount of said promoter metal present on said catalyst ranges between about 0.5 to 5 wt.% based on the amount of iron in the ilmenite and iron carbide, calculated as Fe<sub>2</sub>O<sub>3</sub>, supported on said catalyst.

11. The process of either of claims 9 or 10 wherein the amount of iron present in the ilmenite and iron carbide supported on said catalyst, calculated as Fe<sub>2</sub>O<sub>3</sub>, is between about 2.8 to 8.3 milligrams per square meter of titania support surface.

12. The process of claim 11 wherein the mole ratio of H<sub>2</sub> to CO in said gaseous feed mixture is between 1/2 to 3/1.
