Hydrogenation and L.T. Carbonization  
Properties of Ruhr Coals  
By Giesg, Ludwigshafen, 12 March 1942

The mining of coal in the Ruhr district amounted in 1938 to:

26.58	Mill. t	containing	(35-40% volatiles/pure coal			
			(30-35%			
86.28	"	"	19-30%	"	/	" "
8.00	"	"	13-19%	"	/	" "
6.42	"	"	7-12%	"	/	" "
127.28	Mill. tons	total production.				

Coals containing over 35% volatiles and less than 85% C in the pure coal are considered having good hydrogenation properties.

Low temperature carbonization properties are based solely on the tar yield, without consideration of assortment, constitution and quality of the coke, type of oven and economy. A coal with a minimum tar yield of 10% by Fischer-Schrader is considered carbonizable.

The attached table evaluates the Ruhr coals received and analyzed by us for hydrogenation experiments.

It shows that of 42 coals considered having good to fair hydrogenation properties, 41 coals, or 98%, are carbonizable with respect to the tar yield.

On the other hand, of 45 carbonizable coals, 41 coals, or 91%, may be considered suitable for hydrogenation.

It is apparent, therefore, that all carbonizable coals containing over 35% volatiles are also suitable for hydrogenation. As to the coals containing over 85% C and 30-35% volatiles, there are carbonizable coals in this group, which are not suitable for hydrogenation or only moderately so.

The Krupp L.T.C. coal K-1130, with 86.7% C and 8.2% tar yield is obviously classified as an L.T.C. coal because of the good quality of its L.T.C. coke.

The last 3 coals in the table from the Gelsenkirchen Mining Co. and Matthias Stinnes represent a special group, which do not permit an L.T.C. analysis because of their tendency to swell.

TABLE  
EUROPEAN COALS
