

Abstract on  
OPERATING PROCEDURES FOR THE CHARACTERIZATION AND  
DECOMPOSITION OF ASPHALTS

by Suida and Metz, Petroleum vol. 35, No. 30 (1939), with information on the methods used in Iowa.

Our knowledge on the nature and composition of asphalts is limited. Chemically identifiable constituents acid compounds, saponifiable compounds and other oxygen compounds; 3 compounds present with the hydrocarbons with no information available on their composition. For these reasons, characterization mostly made on the strength of physical data (sp. gr., viscosity). Fractional solution and determination of the size of fractions. These data do not give complete information to judge the practical usefulness of asphalts. They merely characterize a certain condition of the asphalts.

A decomposition is required to draw conclusion on changes in the asphalts, as well as its stability.

A large number of investigators have made many tests and investigations in this field. Richardson was one of the first amongst them, who decomposed the asphalts into:

petrolenes	volatilizable
malthenes	soluble in gasoline
asphaltenes	" in $CS_2$
Carbones	" in $CS_2$
non-bitumens	

Others selected other solvents, and a new idea was finally applied, of using adsorption media. Maronsson and Picard used activated charcoal and bleaching earth. Suida and Kemptner used bleaching earth, and Pöll, finally, used various solvents with bleaching earth. He has made a distinction between petroleum constituents, petroleum resins, asphalt resins and hard asphalts (carbonos and carbonidos; carbonos soluble in  $CS_2$ ; insoluble in  $CS_2$ ; Carbonidos insoluble in all the solvents). Pöll's method was widely acclaimed and has been accepted in literature as a good and exact method for the characterization of asphalts. We may illustrate how frequently and widely opinions differ by saying that Kemptner opposed adsorption media for a while, and returned to them later with Mass used activated charcoal of certain activity.

Hallensteyn took a stand definitely opposing the opinion that the difficultly soluble constituents of the asphalts were hydrocarbons in mutual solution. He considered asphalts as colloidal systems of dispersed C in an oil as the dispersion medium. Results obtained by decomposition hardly can furnish a basis for the separation of asphalts into chemical groups. Asphalts may well be distinguished by their origin. The older an asphalt (geologically) the larger the proportion of the difficultly soluble and most difficultly soluble constituents. Changes brought about by oxidation are manifested by increased proportion of hard asphalts.

while natural or straight run asphalts not changed by oxidation contain higher proportion of soft asphalts, which permits a ready differentiation of blown asphalts from distillation asphalts. All the more detailed investigations show a clear line of demarcation between the oil constituents of the asphalts and the difficultly soluble asphalts, forming a continuous series up to free C.

The molecular weights increase steadily from the oil constituents to free carbon. The systems change gradually from true solutions, through colloidal dispersions, to the coarse dispersions.

All results obtained by the methods of decomposition by solution and flocculation depend on the proportion of amount of solvent to the amount of extract, and in case of flocculation on the proportion of the flocculant to the amount flocculated. When solution and adsorption methods are used jointly, we get not only a greater probability of obtaining reproducible results, but also strictly comparable values for different asphalts. Adsorption equilibria are very sensitive to temperature changes, but independent within wide limits from dilution.

Every possibility of polymerization must naturally be avoided by keeping  $O_2$  absent. There is not a single exact literature reference, according to which either bleaching earth or activated charcoal act as polymerizing agents when no oxygen is present, and the temperatures are low.

All the methods so far developed, including that of Föll, consume much time, and are not sufficiently reproducible. Suida and Motz have developed a method which reduces to a great extent the errors of manipulation by being automatic, simplifies the operating technique and saves much time.

#### Suida-Motz method.

10 g. freshly dried bleaching earth is weighed into an extraction thimble (45 x 123 mm). The thimble is placed in the apparatus, and 200 ml.  $CHCl_3$  added. The mixer head is attached, and by starting the mixer, the earth is uniformly distributed through the thimble. The temperature is maintained at 20°C.

1 g. of the substance to be studied is now weighed into a small glass flask, dissolved in 30 ml.  $CHCl_3$ , the solution carefully transferred to a dropping funnel, and dripped into the extractor maintained at 20° using 30 minutes for the operation. In this way the adsorption upon the bleaching earth is perfect. The mixer flask and the dropping funnel are now rinsed with  $CHCl_3$ , the slow addition to the extractor continued until the solution is syphoned off into the flask.  $H_2$  is led into the flask through a capillary to exclude oxygen as well as to equalize boiling. The flask is set into a water bath. The extraction is continued at 20° until the  $CHCl_3$  running out of the extraction thimble is colorless. The contents of the flask are then rinsed into a dish,  $CHCl_3$  evaporated, and a mixture of petroleum oils and resins is left behind.

A fresh flask is now substituted,  $H_2$  or  $CO_2$  led in through a capillary tube for about 1 hour, until  $CHCl_3$  has been driven off. 300 ml. pyridin are then slowly added through the dropping funnel, and the extraction carried out at  $20^\circ$  with pyridine. The oil bath temperature is now maintained at  $190 - 280^\circ$  (?). The main portion of pyridine is then distilled off at the end of two hours, the residue in the flask precipitated with dilute  $HCl$ , pyridine and water well washed out, and the precipitated asphalt dissolved in benzol or  $CS_2$ .

Asphalt resins remain after evaporating the solvent. A tube in the cooler is now removed, the flask again filled with 300 ml. pyridine and the extraction repeated at  $50^\circ$ . The extract is worked up as before; the remaining residue consists of hard asphalt.

Changes in equipment to meet the requirements in Leuna:

1) removal of solids with pyridine and  $CS_2$  must be done to obtain the total asphalt. If solids are not removed, poor or non-reproducible results are obtained because of the formation of pockets in the Fuller's earth.

2) Oil and oil resin are separated into their constituents by taking advantage of the fact, the oil resins are insoluble in benzol solution if precipitated upon Fuller's earth.

**FLOW SHEET**

Suida and Metz method for the decomposition of asphaltite.

10 g sample + 300 ml pyridine/CS<sub>2</sub> 1:1  
 (heated, filtered, washed.)  
 filtration residue (pyr. + CS<sub>2</sub> insol.) → Filterate (sol. in pyr. + CS<sub>2</sub>. + solvent)  
 evaporate solvent  
 pyr-CS<sub>2</sub> solution

1 g pyr+CS<sub>2</sub> solution  
 add 30 ml CHCl<sub>3</sub>  
 transfer to apparatus  
 add 24 g. terrana in 200 ml CHCl<sub>3</sub>

(3) losses = 100 - ((1) + (2) + (3) + (4))

DECOMPOSITION OF ASPHALTS BY THE SUIDA AND MOTZ (Leuma)

and Scholven methods

HOLD	Leuma (Stall 304) gasoline/middle oil	Politz	Scholven	Gelsenberg
Insolubles in: Pyridine + CS <sub>2</sub>	12.0	14.0	18.5	19.5
Pyridine	17.2	13.7	21.2	18.9
CHCl <sub>3</sub>	19.2	16.4	28.5	20.8
Benzol	20.4	18.9	30.0	21.5
CCl <sub>4</sub>	25.5	33.9	33.0	23.3
S-asphalt in: Benzol	14.4	18.2	29.5	14.0
Pyridine	17.5	21.1	30.3	14.7
Decomposition (Suida and Motz, Leuma)				
Oil	42.2	40.7	46.5	50.7
Oil resin	23.5	29.1	30.7	29.1
Asphalt resin	14.5	5.8	6.4	9.5
Hard asphalt	16.1	22.0	15.2	9.6
Losses	0.7	2.4	1.1	1.1
Decomposition, Scholven				
A asphalt	2.0	2.7	7.4	1.9
B asphalt	1.2	2.5	1.4	0.7
C asphalt	5.1	4.9	0.0	1.8
A + B + C asphalt	8.3	10.1	19.8	4.4
Oil resin	4.7	3.2	16.7	10.1
Oil	69.6	71.0	45.3	66.6

A asphalt = CHCl<sub>3</sub> insol. - Pyrid. insol. B asphalt = benzol insol. - CHCl<sub>3</sub> insol.  
 C asphalt = insol. CCl<sub>4</sub> - insol. benzol Oil resin = CCl<sub>4</sub> sol. - neutr. oil.
